partially concealcul mbout base, in front of antenna with subconfluent punctures. Prolhorax not much longer than wide, sides slightly romuded from base to apical third, and then decreasing to apex, which is abont two-thirds the width of base; with dense concealed punctures. Elytra about one-third wider than prothorax, and not thrice as long, about one-third longer than wide; striate-punctate, but punctures normally concealed ; interstices gently convex, with mumerons concealed punctures.

Length (excluding rostrimm) 4 mm.
Hah. New South Wales: Hawarra.
On the head and basal half of rostrum the seales are mostly ochreons, with a few paler spots. On the prothorax they are mostly ochreons brown or sooty, with a pale obligne stripe on each side, and a less distinct one along the mididle. On the seutellnm they are white. On the elytra they are mostly of a dingy brown, hut on the apical fourth they are of a rather pale ochreons, bounded anteriorly by a curved sooty line, across the middle there are some whitish spots, accentuating some sooty ones, and on the shoulders and near the sentellum there are also some whitish and sooty spots. The whitish spots from some directions appear like freble fascicles. On the muder surface the seales are almost white, and on the legs they are mostly stramineous. The type is probably a male.

> XL- New Oi ientul Pentutomoidea. By E. Beranoti, (J.M.Z.S.

## F̌am. Scutelleridæ.

## Coleotichus ornamentifer, sp. n.

Rather broadly obovate. shining. Head a little less than half the length of pronotum, not quite one-half broader than Iong, almost impunctate, laterally a little simuted somewhat before the eyes, clypens slinhty passing apex of juga, a little constricied in the middle, posteriorly reaching slightly beyond the level of the middle of the eyes; ocelli a little over three times more apart from cach other than trom eyes, placed immediately behind the level of the posterior margins of the eyes; inferior margin of buccule slighty sinuated, first and second joints of antenne equal in length, third onehalf longer than sceond, fourth somewhat shorter than second
and thicl together, fifth as long as fourth; rostrum unt quite reaching posterior end of metastemum, the last three joints subequal in length. Pronotum one-half broader than long, within the slightly rombded and bluntly subelevated antero-lateral margins with a distinct, rather broad, subangular or a litile curved longitndinal impression, the anterior half of which is almost parallel to the margins and extended from the apical angles to near the middle of the margins, whilst the posterior half is parallel to the longitudinal axis of the body; sparsely punctured, lateral borders and cicatrical areas very remotely so, a longitudinal anteriorly slightly raised, posteriorly evanescent median line impunctate; apical margin moderately simuate, obliquely truncate behind the eyes, lateral angles rounded, very slightly prominent, postero-lateral margins a little sinuate. Scutellum reaching apex of abdomen, slightly widening fiom the base to a little beyond it, then subparallel as far as to the middle of the fourth comexival segment, then arcuately narrowing to the broadly and slightly ronnded apex, sparsely pmetured, somewhat more thickly and finely so in the apical fourth; a transverse posterionly rounded basal area not quite reaching the lateral margins very remotely punctured and in the middle impunctate, a slightly raised impunctate median line ruming from the posterior margin of the basal area backwards, but evanescent before apex. Pectus sparingly and very irregularly punctate, anterior flaps of prosternum shaped as in the other species of the subgenus Paracoleotichus, strongly punctured at their base, almost impunctate toward their apical margin. Hemelytra slightly passing a, ex of scutellum and abdomen ; corium not quite reaching apex of fourth comexival segment; exocorinm remotely and extremely finely punctulate, mesocorium and especially endocorium much more strongly (though sparingly) punctured, suture between exocorium and mesocorium three times longer than that between mesocorium and endocorium. Abdomen beneath rather irregularly strigose, but searcely punctured, the middle of the disk and the lateral borders smooth, the longitudinal median groove very distinct from base of venter to apex of fiftl segment, narrower and less distinct in basal third of sixth segment, the apical angles of the segments a little prominent, those of the sixth segment more acute and tooth-like; sixth female ventral segment in the middle a little longer than the two preceding segments together, and twice longer than its lateral margin (including the apical tooth), its apical margin broadly bisinuate, the median apical part of the segment and the female genital segment with a
pale suherect pilusity, the median female genital lobes marly iwice broader than long at their interior margin, but not reaching lateral minges of basal lobes, apical lobes arenately triangular, acute at apex. Colour argillaceons, juga and lateral borders of prothorax, of corimm, and of atudonen reddish orange, lateral margins of clypeus, a median basal fascia to head emitting two vitte to base of elypens, four rounded spots placed transversely in anterior part of pronomm (one at each ent of cicatrices), two lungimdinal bands near middle of posterine portion of fromotum, thee or four spots betwen these bands and the latemal margins, a basal spot to scutellum on each side not far from the angles, a large scutellar marking resembling a written $x$ with tho

end of the bramehes strongly dilated, a curved abbeviated fascia sll each side of the $X$-shaped marking, a sublateral vitta to pleure, a broad anteriorly alibreviatel vita to mesncorium, an interior apical vitti to exocorium, the apieal angles of the abdominal segments, the tanserse sublateral impression behind the spiracles, and a median spot to sixth ventral segment back; hasal area of sentellum (except tho black markings) pale yellow: membane fuseous; all punctures of the argillaceons pans of pronomm and sentellum placed in a small round semipellacid spot of a peculiar watey dark greyish colour mot mitike that of dituted ink; antemisu piccons, first joint, apical half of secome amd basal hals of third joint testaccous; rostrmm, exept first joint, black; legs dak testaceons, femora more or lens suffinsed with fuscons.
langll, of 14 mm , width s.j mm.
Bornen: Samtubeng in Samwak (J. C. Mfouton).
Allied to C: artensis, Montr., hat differing in the very much less pumented hasal area of senteflum, henerer sixth ventral segment, and several onter details. The coloming is probably variable as in the other species of the gemus, but in the
colour-markings of the scutellum none of the numerous varieties of artensis seems to be similar to the single known specimen of the Bornean species.

The species of Coleotichus principally inhabit the islands of the Pacitic Ocean. One species is known from Sumatra, but none had previonsly been found in any of the other great sunda islands.

## Fam. Pentatomidæ.

## Subfam. Aryine.

Schouteden has divided Canthecona, Am. S., into two genera, separating the Astatic species as a distinct genus, Cantheconidea. The latter genus he divides into two sections, A and B, corresponding to Stal's division $a a$ and $a a a$ of Cauthecona. These sections differ much more inter se than the section B of Cuntheconider differs from Canthecona, and must in my opinion be regarded as distinct genera with the following characters :-

The sides of the metasternum strongly carinately raised above the level of the coxe, freely produced forward and backward between the coxe. Tibix cylindrical, only toward the apex flattened or slightly sulcate. The males with no sericeous patches on the renter; apical marcin of sixth male ventral seguent broadly bisinuate. (Type: C.jucana, Dall.)

Cantheconidea, Schout.
The sides of the metasternum a little raised, but not produced forward and backward. Tibie conspicuously sulcate down their whole length. The males with a large sericeous (stridulatory ${ }^{?}$ ) patch on each side of the renter extended through the fourth and fifth segments; apical margin of sixth male ventral segment broadly unisinuate. (Type: C. furcillata, Wolff)

Eocanthecona, gen. nov.
Asopus chrysopterus, H. Sch., from the island of Guam, has remained unknown to later authors, but has in all catalogues been placed in Canthecona, and later in Cantheconidea; yet from the description and figures, and from the fact that Herrich-Schäffer placed it in a division characterized by "Vorderschenkel ohne Dorn," it is clear that it has nothing to do with this group of genera. 'There can be little doubt that it belongs to an undescribel genus.

## Locanthecona eburnea, sp. 11.

I vory-white, lateral margins of juga, upper part of antenniferous tuberches, a spot on each side of vertex enclosing the necllus, a tramsverse pronotal spot outside each cicatrical alea inwardly continued round this area, a subguadrate spot on the commexival incisures, an irregular spent on propleura and mesoplena, mesostemum (exeept the median ridye), posterior maryin of orificial sulcu*, a narrow enved sublateral fascia t) motapleura emitting a short branch to the lateral margin, a spot at base of epipletra, a short transverse sublateral streak on second ventral segment, a narow curved sublateral fascia on the last four ventral segments connecting the basal margins with a point a little behind the spiracles, a spot at basal angles of third ventral segment, and a median spont on sixth ventral segment, shortly continued over the fifth, brassy greenish black; humeral processes of prothorax, a deep tiangular fovea at basal angles of scuteltum, dorsum of abdumen, and a median vitta to female genital segment picent; ; membrane fuscous, an oblong spot on cach side before the apex hyaline. Head above sparsely punctured "inh fuscous, an oblique oblong area at anterior part of eyes impunctate, first three joints of antemm testaccous, apex of llict broadly fuscous, last two joints fuscous black with a broad basal ochraceous ammatan, second, third, and fifth juints subequal in length, fourth a little longer, rostrum ivory-white, last joint castancous. Pronotum, scutellum, corimm, and comexivum smooth and impunctate, with the following exceptions: pronotmm with some functures between the cicatrical areas and the apical margin, a ow of punctures immediately within the lateral margins, and numerons partly thick-set punctures which form a fascia connecting the humeral processes and emitting from its midfle an irregular contimation forward to a little beyond the middle of the pronotum ; scutcllum with scattered punctures arranged in a thiangular basal area and an oblong area on each side near apex of frena; exocorium with a row of punctures reaching from the base to beyond the middle, then irrecularly sparsely punctate, mesocorinm with an oblong punctured anea hehind the middle near the radial vein, sparsely punctate in its outer apical area, and at the inner margin with a row of punctures duplicated behind the middle, endocorium hehind the middle with a row of punctures; connexivum with a few strongly impressed points in the greenish-black incisural spots, except the himdmost ; the puncturation of pronotum, scutellum, and cotium fuscons,
coarse on pronotum, somewhat finer on scutellum, and still finer on corium. Prothorax with the autero-lateral margins sinuate behind the middle, slightly rounded and distinctly crenulated between the simosity and the apical angle, humeral processes directed outward and a little forward, their posterior margin with a blunt tonth at some distance from the acute apex. Hemelytra passing apex of abdomen by about one-third the length of the membrane, apical margin of coriun somewhat rounded. Pleura strongly and sparsely punctured with greenish black and fuscous, lateral and posterior borders of metapleure impunctate. Abdomen with the apical angles of the segments a little prominent, venter finely and remotely punctulate with fermginons, spiracles pale brownish. Legs ivory-white, femora dotted with reddish brown, apex of femora and of tibie, and base of tibize mottled with greenish black or fuscons, tarsi more or less infuscated; fore tibie a little dilated at apex.

Length (excl. membrane), of, 12 mm .
Philippine Islands: Mount Makiling, Lnzon (C. F. Buker).

In some specimens the punctures hetween the cicatrical areas and the apical margin of the pronotum, the row of punctures within the pronotal lateral margins, and the puncturation on the outer half of the pleure are lacking.

Very remarkable by having the pronotum, scutellum, and corium for the most part quite smooth and impunctate, and in this charac'er differing from all previously known species.

## Sulfam. Phillocephalines.

Uddmania, gen. nov.
Body oblong, depressed. Head small, a little broader than long, rather strongly sinuated before the large prominent glubose eyes, vertex convex, ocelli wide apart, placed near the eyes, clypeus somewhat bent down in its apical part, juga a little longer than clypeus, but neither meeting nor convergent in front of it, rounded exteriorly before apex, antemiferous tubercles blunt at apex, the greater part of them visible from above, buccula very strongly elevated, a little higher behind than before, seen from the side rounded at anterior end, vertical at posterior end, their inferior margin straight, rostrum reaching anterior coxæ, its second joint almost reaching posterior end of bucculæ, antennæ slender, first joint somewhat incrassated, passing apex of liead by about half its length, the three following joints
subequal in length, each much longer than first (last joint wanting). Pronotum rather deeply arenately simate at apex, antero-lateral margins deoply ohtusangularly simated in the middle, owing to the hameral angles being produed in a subtriangular process directed obliquely forward and outwart, these margins subacnte, irregnarly denticulated from pronotal apical angles to hase of hameral processes, these processes not reaching the leval of the pronotal apical angles, their margins entire, not toothed, pronotal hasal margin straight. Sentellum longer than broad, about reaching middle of abdomen, lateratly simated considerably behind the midalle, postfrenal part namow, nearly twice as long as broad, its sides subparallel, apex roumded. Mesostemum somewhat convex, keched in the middle. Orificial sulens rather short. Hemelytra when closed scarcely broaler than, but entirely covering, the abdomen, corinm much longer than scutellum, costal margin slightly rounded, apical angle acnte, apical margin straight, ramula throngh a little less than its basal half closely following the radial vin, then somewhat deviating from it, ending not far behime middle of coriun, membrane with the veins forked, the outcomost and the three intenor ones simple. Abdomen laterally slightly rounded, ventral lateral border a little concave, apical angles of the segments searcely prominent, those of the last segment ( $\delta$ ) broadly lobately rommed, spiracles obliquely transverse, placed in the posterior declivity of a small callus, more remote from the lateral than from the apieal margin of the segments. Legs rather slemer, fore tibiae beneath with a small indentation in the apical half preceded by a short spinule, lirst joint of all tarsi very slightly longer than the two others tugether, and more robust.

This genus is allied to Cressona, Dall., from which it differs in several details in the structure of the head, the much shorter, more divergent, and not servate hameral processes of the prothoras, de.

Named in memory of the first Fimmish entomologist, Isala Udiman, whose illustrated dissertation' Nova insectornus species' (Ahare, 175.3), contains for that time very gool deseriptions of a lumdred species, later specitically named by Linnsens and others.

## Uildmania repallida, sp.n.

Dull, above pale ochaccons, finely and dispersedly punctured with backish and fuscous, still more finely and remotely
so on head and corium, beneath still paler than above, rather sparsely but less finely punctured with black; a narrow median vitta ruming from apex of pronotum to apex of secutellum, a percurrent pleural vitta, a broad ventral vitta on each side near the middle, and a rather large oval sublateral area to each ventral segment impunctate, the ventral vittæ, however, with sundry black points arranged in an indefinite and irregular longitudinal row, venter at the median basal part and on each side near the median line here and there tinted with ferruginous or sangnineous; antemiferous tubercles above, antero-lateral margins of pronotum from apical angles to base of humeral process (including the teeth), and a small oblong spot behind middle of corium at apex of rimula black; membrane pellucid, with scattered romed and shortly linear fuscous-black specks. Head onefifih broader than long, juga finely obliquely wrinkled and with the scanty puncturation very pale brown. Pronotum feebly transversely rugose, humeral processes slightly shorter than their basal breadth, their anterior margin rounded toward the apex, their posterior margin straight, a little longer than the part of the postero-lateral margin lying before the base of corium. Scatellum feebly transversely rugose. Hemelytra ( ठ) slightly passing apex of abdomen, corium reaching somewhat beyond base of pemultimate comexival segment. Abdomen with blackish spiracles, sixth male ventral segment in the middle slightly shorter than fifth, male genital segment not quite reaching the apex of the lateral apical lobes of the last ventral segment, its apical margin obtusangularly sinuated in the middle. Legs very remotely and finely dotted with brown.

Length, ơ, 19 mm .
Philippine Islands: Mt. Makiling, Luzon (C. F. Baker).

## Tetroda denticulijera, sp. n.

Brownish ochraceous, thickly and finely concolorously punctulate, less thickly and more superficially punctate on the venter, scutellum at the sides from basal angles to apex of frena with a dark fuscous posteriorly tapering stripe, and immediately inside this with a transversely rugose whitish vitta which, behind the frena, occupies the lateral margins themselves, tapering posteriorly but almost reaching apex, membiane greyish hyaline with pale brown veins, venter with a whitish callus immediately before each spiracle. Head about one-third longer than broad, the lateral margins with a short acute spine a little in front of the eyes, juga
directed straight forward, lanceolate, very uarrowly rounded at apex, their freely projecting part as long as the distance between the apex of clypens and a line connecting the ocelli, and as broad at its base as half the distance between the ocelli. Pronotum with a low laterally evanescent ridge between the humeral angles, and between this and the cicatrical areas with a few transerse ruge, the apical processes slighty passing the level of the apex of the clypen*. Hemelytra (of) somewhat passing base of dorsal genital segment, corium not quite reaching apex of antepemblimate comexival segment, its apical margin slightly rounded. Abdomen in the interior half of the largely exposed comnexivum with numerous short, sublevigate, vermicularly tortuous, impressed, fuscous lines arranged in a longitudinal band ; beneath on each side a little within the lateral margins with a longitndinal band, and somewhat more inwardly at the apical margin of the segments (except the sixth) with a transverse fascia, all composed of similar meandering lines; femate dorsal genital segment somewhat broaler than head, its apical margin broadly and slightly sinuate.

Length, of, 17 mm .
'I'onkin.
In having a small acute lateral spine a little in front of the eyes this species is allied to I'. oltusa, Dall., but the juga are narrower and less rounded at apex, the anteocular spines are concolorous with the head, the scutellum is quite differently coloured, and the venter is less thickly and less strongly punctured without the large transverse impunctate lateral fovee so characteristic of olitusa.

## Sulfam. Achithostometine. <br> Proctophuntasta minax, sp. In.

Shortly oval, above black; head with the lateral margins from within the eyes to beyoud middle of juga, a longitudinal band on juga, a line in the apical half of clypens, a spot inside each eye, an clongate lanceolate spot reaching from lase of clypeus to base of head, and two transverse basal spots on each side yellow ; pronotum with the antero-iateral and postero-lateral margins, seven spots (the median one larger and subquadrate) on the transverse elevated subapical area, and five spots immediately behind the impressed line posteriorly temmating that area stramineous, the two onter ones (on each side) of the latter spots oblique and removed from the oblong, somewhat callose median spot ; scutellum Ann. © Mag. N. Mist. Ser. S. Vol. xv. 33
with a spot near the basal angles and a large transversely oval bloteh almost reaching the lateral margins immediately behind the middle yellow; corium with the basal part of the costal margin yellow, and with an elongate triangular whitish area in the basal half of the mesocorium ; connexivum with a yellow spot at the apical angles of the four first segments, fifth and sixth segments entirely stramineous, except their black apical spines; membrane hyaline, shaded with fuscous toward base; head beneath and pectus stramineous, the former with a narrow fuscous streak before the antemniferous tubercles, middle part of all sterna (except median keel of mesosternum), three longitudinal bands on propleuræ, the outermost and innermost of which are transversely continned inwards from both their ends, a transverse angular fascia in anterior part of mesopleure together with their whole exterior and posterior parts, and the metapleure (except orificia, posterior border, and posterior half of lateral border) fuscons black; venter piceous brown, a yellow spot at apical angles of the first four segments, lateral borders of fifth segment, the whole sixth segment, and the male genital segment stramineous; antenne fuscous, first and second joints (except outer and inner margins of first), and the extreme basc of the following joints dark testaceous; rostrum stramineous, last joint fuscous black; legs fuscous, femora (except the dusky apex) dark fulvous with a rusty tint, toward the base, together with trochanters and coxæ, whitish, a spot on coxæ fuscous. Head impunctate, but with an impressed punctured longitudinal line on each side of vertex before the ocelli, which are a little more remote from each other than from the cyes, first joint of antemme passing apex of head by one-third its length, second joint a little shorter than third which is at least one-fifth shorter than fourth (fifth wanting), rostrum reaching apical margin of third ventral segment. Pronotum strongly and rather thickly punctured, the elevated subapical area and the pale spots behind it smooth, lateral margins straight. Scutellum coarsely and rather thickly punctate, postfrenal part more fincly punctured, the pale areas impunctate, lateral margins straight. Pectus impunctate, a transverse row of fuscous punctures near apical margin of prosternum, posterior part of propleuræ finely and remotely punctate with fuscous, median keel of mesosternum low and very narrow, slightly dilated anteriorly between the fore coxæ. Hemelytra passing apex of genital scgment by about one-fourth the length of the membrane, corium as thickly punctured as the scutellum but less strongly so, mesocorium in its interior part with three regular rows of
punctures, the outer two rows somewhat curved behind the middle, exterior part of mesocorium and apical part of exocorium remotely punctate. Abdomen impunctate, beneath bluntly roof-shaped in the make, sixth male ventral segment in the middle somewhat longer than fifth, its apical spines rather strongly arcuately upturned from base to apex, almost sickle-shaped, passing apex of membrane, male genital segment subtriangular, almost as long as the last two ventral segments together.

Length (excl. membrane and anal spines), $\delta^{5}, 6.8 \mathrm{~mm}$.
Philippine Islands: Mount Banahao, Luzon (C. F. Baker).

In the colour-pattern of the upper side similar to $P$. satanas, Bredd., but the second antemal joint is much shorter, the pronotum more strongly and regularly punctate, the yellow submedian area of the scutellum not punctured in the middle, the anal spines are more curved and upturned, and the underside of the body and the legs somewhat differently coloured.

## Proctophantasta minitabundus, sp. 1.

Shortly oval, pale testaceous with the following piccous markings : interior margin to juga, a narrow sublateral vitta to juga anteriorly occupying the margin itself and posteriorly widening into a spot inside anterior part of eyes, two somewhat outwardly curved vittæ on vertex, a spot between ocelli and eyes, upper side of antenniferous tubercles and a streak before them, apical border of pronotum, a band inside its anterolateral and postero-lateral margins, an irregular transverse fascia, interiorly widening and enclosing a fulvous spot, on each side of the transversely elevated pronotal subapieal area, the transverse linear impression posteriorly terminating this area, an oblique vitta not far from the posterior pait of the pronotal antero-lateral margins and parallel to them, reaching the postapical transverse callosity, a spot behind middle of corium, its interior and apical margins and the apical half of the costal margin, three vitte on propleure quite similar to those of P. minax, middle part of mesosternum (except median keel), a spot at base of middle acetabula, a short vitta close to exterior margin of mesopleure, anterior, exterior, and posterior margin of the evaporative area, and an abbreviated transverse fascia a little within the lateral margins of the ventral segments ; connexivum black, each segment at the interior margin "ith two rectangular fulvous spots, one near base, the other at apex, and at the exterior
margin with an elongate triangular fulvons spot reaching from apex to beyond middle; membrane hyaline; ventral segments with a pale yellow spot at the apical angles; antenne with the first two joints testaccous, the basal one with a fuscous streak on each side, the last three joints fuscous black, with the base testaceous; roatrum and logs pale testaceous, the former with the last joint fuscous. Head impunctate, but with an impressed punctate area at the exterior base of the juga and an impressed punctured longitudinal line on each side of vertex before the ocelli, which are as remote from the eyes as from each other, antemne as long as the body without the anal spines, first joint distinctly passing apex of head, second as long as third which is a little shorter than fourth and conspicnously longer than fifth, rostrum reaching apical margin of third ventral segment. Pronotum, except the smooth transverse elevated subapical area, strongly but very irregularly punctate, the whole posterior part (behind the elevated transverse area) with an anteriorly widened median line, an oblique sublateral vitta, a rounded spot inside this, and some smaller anterior spots and waved transverse lines impunctate, pronotal lateral margins straight. Scutellum coarsely punctate, postfrenal part finely punctulate, a small callus at the basal angles, a percurrent median line, and the apox impunctate, the lateral margins slightly sinuate at apex of frena. l'ectus impunctate, a transverse row of fuscous punctures near apical margin of prosternum, posterior part of propleure remotely punctured with fnscous, median keel of mesostemum low and very narrow. Hemelytra passing apex of genital seginent by nearly onethird the length of the memb ane, corimm strongly punctured, mesocoilum in the basal half of its exterior border impanctate. Abdomen impunctate, beneath in the female rather deeply and broadly longitudinally sulcate down the middle, the furrow narrower and less decp in the sixth segment, at the base of which it is narrowly interrupted, apical spinelets of fifth segment somewhat curved, apical spines of sixth segment a little longer than genital segment and last ventral segment taken together, passing apex of membiane, directed straight backwards, but curved a little outward at the base and a little upward at the apex.

Length (excl. membrane and anal spines), 아, $7 \cdot 5 \mathrm{~mm}$.
Philippine Islands: Mt. Banahao, Luzon (C. F. Baker).
More nearly related to $P$. colax, Bredd., than to any other known species, but very distinct in several characters.
'T'o Breddin's very good generic description I have only to atd that the evaporative area is large, tramsversely oval,
oceupwing the greatest part of the metaplena, and very slighty scupptured. Distant (Rhynch. Brit. Ind. iv. p. fiti) has also deseribed the gemus (Inder the wrong name "Probophantusta") and says in the deseription: "tibite longitulinally grooved." Shouli the tihie really prove to be suleated in the spreies described by Distmut, this would be a must unsmal and aberrant specific character of that species, as the cylindrical non-suleate tibise is one of the primeipal chamacters of the Acanthematime. I have seen no member of this subtamily with furrow ed thbia.

Pive species of this cmions genus were previnusly kunwn, mefrom Ceylon, two from Sumatra, one from Java, and one from Borneo.

## XLI.- Notes on the Gemus Nyctophilus. By Oldfield 'I'homas.

(Published by permission of the Trustees of the British Musemm.)
When describing the new genus Pharotis last year I published * a cursory survey of its ally, Nyctophilus, and tinding out in what direction further material was most urgently needed, I made an appeal to the authorities of the Australian Museum, Sydney, for specimens from Eistem Australia.

Through the kinduess of Mr. A. R. McCulloch, that appeal has been most liberally responded to, and I have been entrusted with their whole collection of the gemus, numbering no less than 42 specimens from various localities, all preserved in spirit, thus supplementing the British Museum material, which is largely in skin.

On studying these spirit-specimens I limi that most useful differemtial characters may be dation buth from the development of the nose-leat, hitherto supposed to be tho same throughout the genus, and from the structure of the hone to which I have recently drawn attention in squirrels, tho baculum or penis-bone.

The facial membranes consist, firstly, of a definite semicircular leaf surmomenting the nostrils, with or without a median notch in its upper edere, anl, sicondly, of a rombded elevation behind it, more or less divided centrally imo two halves, and varying in its development in three different degrees, which may be briefly described as follows:-

1. Elevation quite low, rommled, nearly miformly hairy, division into two scarcely perceptible.

> - Inn. \& Mã. N. II. (8) xir. I, 38.3.
